

CONCLUSION:

1. Linear Search:

We successfully implemented linear search to find the required element from an array. The algorithm checks each element one by one from the beginning until the target element is found or the entire array is searched. It is simple and easy to implement and can be used for both sorted and unsorted arrays. However, its execution time is comparatively higher for large arrays. Therefore, linear search is suitable for small arrays or datasets.

2. Binary Search:

We successfully implemented binary search to find the required element from an array. The algorithm repeatedly divides the search range into two halves and compares the middle element with the target element. It is much faster and more efficient than linear search for large datasets. However, the array must be sorted before applying binary search. Therefore, binary search is suitable for searching elements efficiently in large sorted arrays.
